CONTEXT-AWARE COMPANION AGENT

The Agent That Notices Without a Word

Context Awareness beyond the computer, about the person

> **A partner who noticed what you looked at with longing, remembered it, and brought it back to you.**
> **That feeling of being understood.**

Nunchi turns that feeling into an agent.

The 4-step lifecycle of the demo agent

01 Watch together

When the user presses start, gaze calibration runs automatically, and the agent watches the screen with the user.

02 Notice interest

When the user's gaze rests on one spot, the agent recognizes the scene and records the user's expression at that moment (smile, surprise, frown).

03 Ask first

When the user looks at something intently, the agent speaks first. It lowers the video volume while talking and stops when the user starts speaking.

04 Find and tell

Using video metadata, subtitles, and web search, the agent finds related information and presents it, or switches the screen.

Awareness Stack

Gaze	EyeTheia estimates gaze with iTracker ONNX on WebGPU over the MediaPipe face mesh
Face & gesture	One camera recognizes smile, surprise, and frown, nods and head shakes, and five hand gestures
Memory	Each gaze shift logs the scene and expression in time order, referenced during conversation
Voice	Silero VAD detects speech, Qwen3-ASR transcribes, Claude Haiku 5.5 streams the reply, and Sera TTS speaks it
Agent	Claude Sonnet 5.5 on pi-agent-core uses web and news search, YouTube search, Danawa price search, and screen look-back tools

Web for the demo, app for the product

Demo · Web

The demo runs on the web so anyone can try it from a link, with no install.

↓

Product · App

Shipped as an app, all data except LLM API calls stays on the device.

With local models, no data has to leave the device at all.

People move toward products that move them.

Until now, agents have advanced by focusing on how people use computers. The latest front of this approach is called Context Awareness, which lets agents read your work history.

Stepping outside that view of Context Awareness, we brought in eye tracking, until now consumed only as content, and

an agent that touches emotions was born.

What if an agent moved you, beyond convenience?

Being moved comes from detail,
and detail comes from the person.

Extensions

Gaze calibration

Data augmentation alone can reduce calibration and handle a wider range of head positions.

Expression & mood

It recognizes only smile, surprise, and frown today, but linking screen history and expressions on a timeline can extend it to build emotional context.

AI glasses

If the platform moves to AI glasses, it can follow and offer a better-suited experience, because it finds what the user looks at in the environment, not just what the glasses camera captures.

Fit with ads

Knowing what the user is interested in makes it a good fit for many ad models.
